The new system will be used by the SSH client application to create a dynamic algorithm for the authentication of the client computer to the remote SSH server. Once the server and the client are connected, the server will create the needed keys in the following manner: It is generated from a temporary key, which is then stored in the client machine and is generated from a master key that is stored in the server. The keys are generated using a dynamic key exchange and the SSH protocol. Sending private key to the server The client should send his public key to the server after connecting to it. It can be done through the command line in order to specify that the public key is required by the server: The client now has to request the connection to the server and enters the public key in the following manner: Client private key is not sent to the server as it is created by the client. Once the server and the client are connected, the server can use the server private key to generate an authentication code that is sent back to the client. The client uses the algorithm in order to authenticate the server public key to generate the authentication code. There are some key differences between SSH and

SFTP that you should know about before you decide which one to use. SFTP is used for file transfers, as opposed to SSH which is used for authentication and encryption. Use SSH for Authentication If you are sending data to a server over SSH then the data is encrypted so that your data is secure. SSH is not commonly used for file transfers as it is too resource intensive. SFTP is used for file transfers. There are some alternatives to SSH and SFTP. SFTP + SSL Internet services often have protocol choices. FTP uses a port number that isn't unique and HTTP uses a port number that isn't unique either. One way to overcome the port problems is to use the SSL protocol. The SSL port is more than 2000 times more common than FTP and FTP is much more secure. Transport Layer Security This is the main part of the protocols, that will allow you to transfer files and documents between computers. This is the difference between FTP and HTTP. The difference is that HTTP is designed to be a user-friendly protocol that can be used by the general public. It is written by people who would like to give access to the web from the web, while FTP is designed to be a secure protocol for transferring files. Transport Layer Security Protocol 1d6a3396d6
