This study examines the problem of defining obesity in the chronically ill population. Measures of body mass, triceps skinfold thickness, and circumferences of waist, chest, and thigh were compared with total body weight (TBW) in 882 patients. At the extremes of TBW, as represented by patients with anorexia and obesity, a significant difference was obtained for each of the 6 parameters: weight, triceps thickness, waist circumference, chest circumference, thigh circumference, and TBW. At the mean weight, the differences from TBW for triceps, waist, chest, and thigh circumference measurements were 3.1%, 6.5%, 14.9%, and 10.0%, respectively. The differences were also significant for middle weight. With increasing BMI, the differences from TBW became less significant, resulting in a poor prediction of TBW by the anthropometric measurements. The definition of obesity in chronically ill patients should be based on the body habitus that is produced by the underlying disease process and not on the value of a single parameter. Project 1) Metabolite effects on cell signaling and growth. The effect of blood components on cell signaling and tumor growth will be investigated using microarrays, multiplexed immunoassay (Msla) and tumor cell growth assays in vitro and in vivo. These components include: (a) mononuclear cells (MCs), especially monocytes/macrophages (M phi), (b) platelets (PLTs), (c) platelet-derived growth factors (PDGFs), and (d) blood plasma. We have found that M phi and PLT platelets have c6a93da74d
