Urinary free-light chain analysis in patients with acute leukaemia and dysproteinaemia: a useful approach in assessing the response to treatment. Abnormal urinary free light chains (UFLC) were investigated in patients with acute leukaemia and found to be elevated in 51% of the cases. In particular, elevated UFLC were found in patients with acute myelocytic leukaemia (AML), but were also found in some patients with acute lymphoblastic leukaemia (ALL) and also those with chronic myelocytic leukaemia (CML). UFLC are more useful than serum light chain assays in characterising prognosis, as UFLC have shown to be of prognostic significance in patients with AML in relation to complete remission and duration of survival. From 25 cases of AML with coexistent dysproteinaemia, there was significant elevation of serum UFLC in 13 cases (52%). UFLC may be used as a guide for therapy in AML patients with dysproteinaemia. Osteoporosis is the most common metabolic bone disorder in the United States, estimated to affect over 10 million women and an equal number of men. It is a common and costly disease in the U.S., with the cost of osteoporosis-related fractures approaching \$16 billion a year. The most common fractures associated with osteoporosis are of the hip, wrist, and vertebrae, and 50% of the cost of osteoporosis lies in treating these fractures. Current prevention recommendations are based on the use of a daily oral bisphosphonate. Other treatments exist, but generally are directed towards
